20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report details the study effort and testing conducted to design a more optimum rifling profile for the Advanced Medium Caliber Aircraft Weapon System (AMCAWS 30MM) ammunition. Several critical parameters such as bearing stress and torque have been identified and their importance to the ultimate survivability of the band assessed. These critical parameters have been incorporated into a preliminary model to predict the success or failure of a given band and barrel combination.

ABSTRACT

Quantitative values for the interaction of several candidate rifling profiles with the AMCAWS 30 ammunition were required so that a replacement for the original AMCAWS 30 barrel could be selected. This effort is primarily directed to that task.

A secondary effort was to document the process of deciding which candidate configurations would most probably be successful. There are several parameters arising out of this work designated as critical (such as bearing stress) and these critical parameters are included in a coarse model to predict success or failure of a given band and barrel combination.

BACKGROUND

Quantitative values for torque and rotating band stresses for AMCAWS 30mm projectiles were required to meaningfully evaluate different types of barrel twists. Displacement, velocity down barrel, and chamber pressure at various time increments were used as input for a computer program (Appendix A, Barrel/Torque Comparisons) that calculated, as its principle output, torque, bearing stress, and shear stress at the rotating band for each time increment. The interior ballistics data was based on an interferometer trace obtained at the Hercules, Inc., test range in Magna, Utah. This trace, Figure 1, is of excellent quality and is one of the best obtained. The particular round examined had essentially nominal chamber pressure, action time, and muzzle velocity.

Six barrels with different twist functions were compared in the program using the same interior ballistic parameters. The barrel types were: (1) current Rock Island Arsenal produced barrels (RIA); (2) current Hercules barrel (Hercules); (3) constant twist barrel and exponential gain twist barrels with exponents of (4) $N = 1.6$, (5) $N = 1.8$, and (6) $N = 2.0$. These barrels are fully described in the description of barrels.

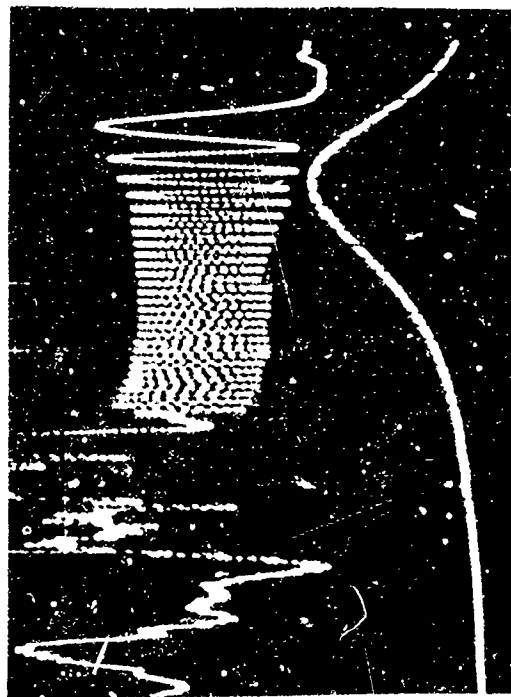

The work to obtain torque and stress values was started as part of a routine investigation to complement the AMCAWS 30mm development work, but the work pace was accelerated when in-flight pictures indicated some stripping of bands (but no instability) on some rounds

fired in the RIA barrels. This stripping was first noticed in June 1973. Work was begun on this effort in late August 1973, at which time the RIA and Hercules barrels were in use. The decision to fabricate a constant twist barrel and an $N = 1.6$ twist barrel was made in September 1973 and these two barrels became available at Rock Island in June 1974. The firing tests were conducted in late October 1974. The computer program itself was extensively rewritten after July 1974 to make use of a CALCOMP graphics system that became operational in Rodman Laboratory during that month.

DESCRIPTION OF BARRELS

1. RIA BARREL. This is an 85-inch barrel made to Rock Island Arsenal Print 74D40070. This barrel has a 1.0 inch throat, free run to 4.0 inches, gain twist to 73.25 inches and constant twist at an 8°58' exit angle to the muzzle. The equation for the twist was obtained by fitting a curve to the x-y layout coordinates. The equation is $y = B_0 + B_1 (X-4.0) + B_2 (X-4.0)^2 + B_3 (X-4.0)^3 + B_4 (X-4.0)^4$. The coefficients are listed in the Barrel/Torque Comparisons program in subroutine AAMC 30 (Appendix A).

2. HERCULES. This is an 89-inch barrel. This barrel has a 1.0 inch throat and gain twist to the muzzle at an 8°5' exit angle. The barrel has no constant twist exit portion. The equation of the rifling layout is:

$$Y = .01008 (X-1.0)^{1.5}$$

3. CONSTANT. This is an 85-inch barrel with a 1.0 inch throat and constant twist throughout the remaining barrel length. The rifling angle is 8°58'.

4. N = 1.6. This is an 85-inch barrel. This barrel has a 1.0 inch throat, gain twist to 81.0 inches and constant twist to the muzzle at an 8°58' exit angle. The equation of the rifling is:

$$Y = .00641042 (X + 14.1582)^{1.6}$$

The gain twist function in this barrel starts with a rifling angle of 3°0' at X = 1.0 inch and gains to 8°58' at X = 81.0 inches.

5. N = 1.8. This is identical to barrel N = 1.6 except the gain portion of rifling equation is:

$$Y = .00208633 (X + 25.9727)^{1.8}$$

6. N = 2.0. This is identical to barrel N = 1.6 except the gain portion of rifling equation is:

$$Y = .000658627 (X + 38.78559)^{2.0}$$

All the barrels described have 20 lands. The depth of groove for the RIA barrel is .019 inches. The groove depth for the remaining barrels is .025 inches.

The notation N = , refers to the type of barrel that has an initial rifling angle of 3° with an exponential gain twist portion and a constant twist exit portion. N = barrels include the N = 1.6, N = 1.8 and N = 2.0 barrels.

INTERIOR BALLISTICS PERFORMANCE

The AMCAWS 30mm round (Figure 2) is a fully telescoped, cased-consolidated round that is currently designed to operate in a stop mode. The primer is struck, which ignites a 45-grain booster charge. The ignition of the booster debullets the projectile and forces it into the bore where, after a total travel of generally less than 5 inches past the barrel face, the projectile stops (thus a stop mode). The hot gas from the booster also acts as an igniter for the 3000 grain consolidated main charge, which causes the large pressure rise that drives the projectile out the muzzle at about 3600 ft/sec.

The set of interior ballistics data used for the barrel comparisons was obtained by considering the round ballistics to be composed of three separate segments: (1) the velocity, position, chamber pressure, and time data points after primer strike and up to the projectile stopping in the bore; (2) the data points between stop and restart; and (3) the data points after restart to muzzle exit. These three regions and the times of occurrence are illustrated in Figure 1.a., which is an interferometer trace of a firing conducted at Hercules, Inc., Magna, Utah.

Figure 1.a. shows the total event with time progressing from right to left at two milliseconds per centimeter. The microwave pulses show that initial movement of the telescoped projectile accounted for

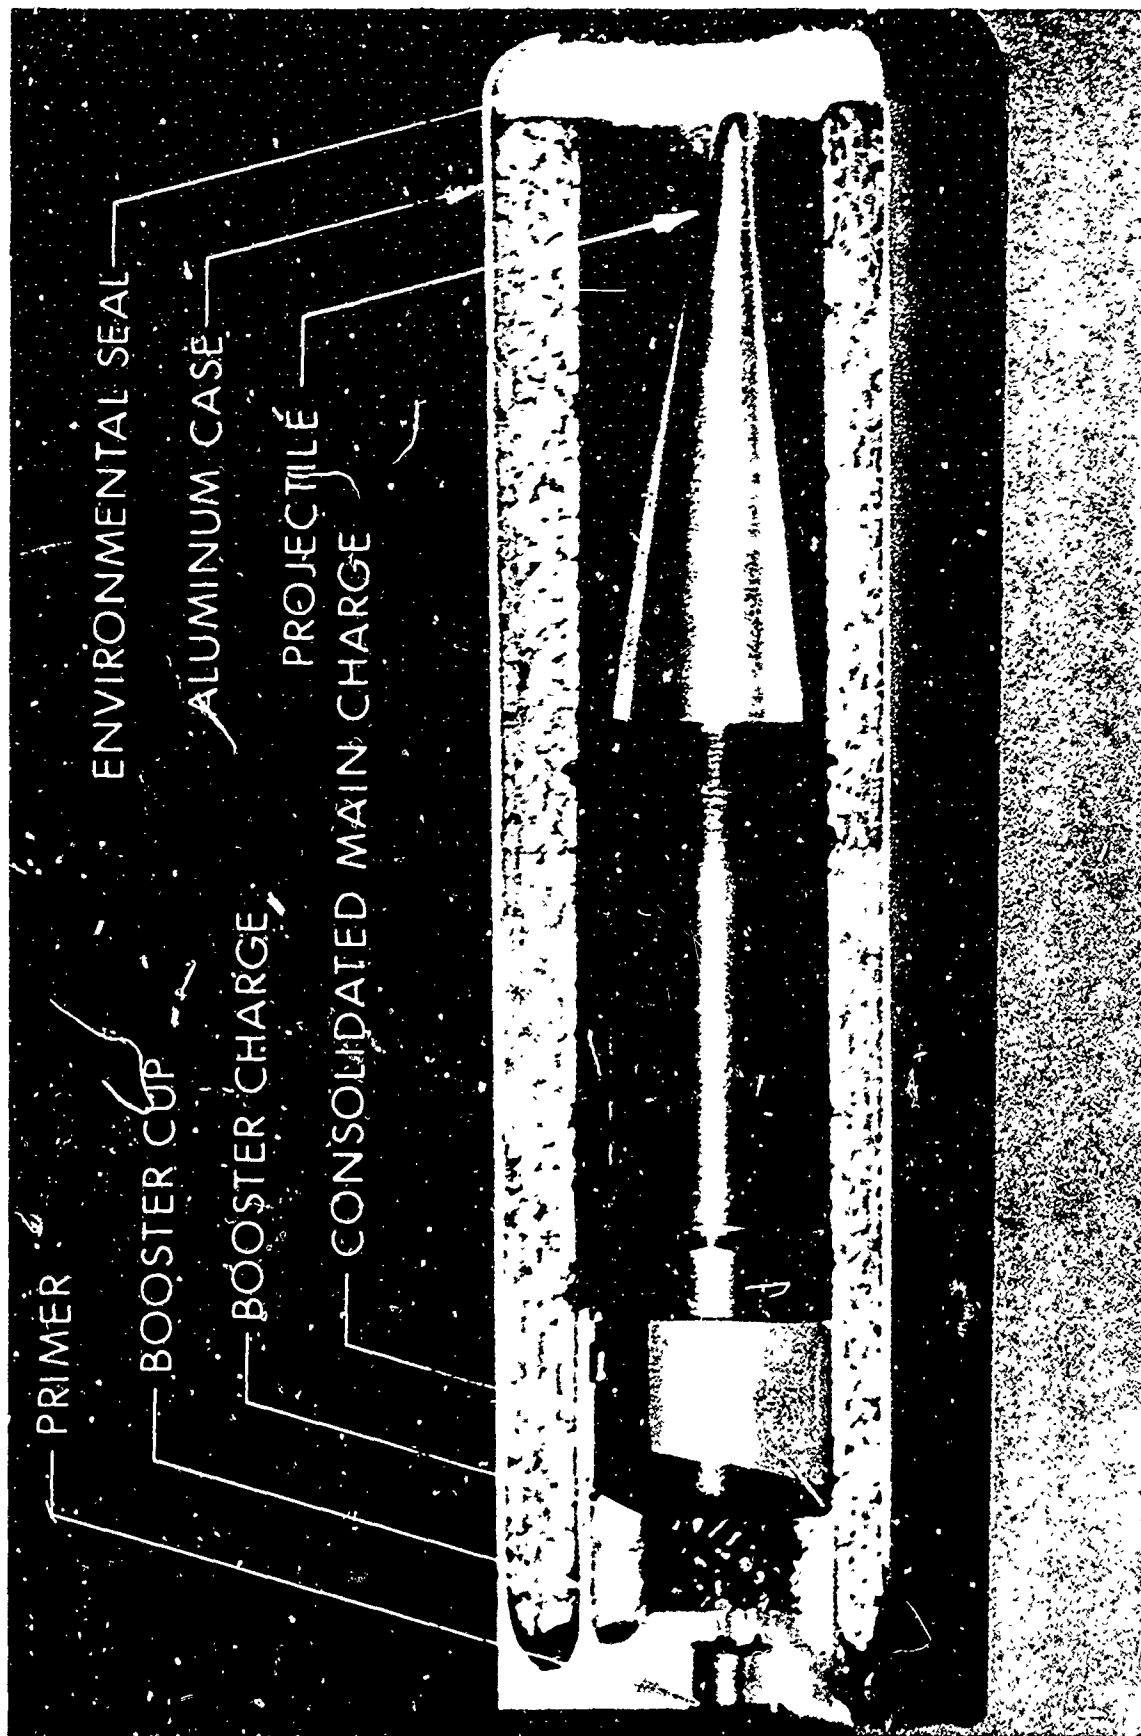

FIGURE 2. AMCAWS 30MM ROUND

about 3-1/4 cycles in about 3 milliseconds. The calibration factor for this firing is 2.567 inches per cycle, thus the 3-1/4 cycles indicates that the nose of the projectile moved approximately 8.34 inches before stopping. Using values of 4.4 inches between the projectile nose (point of reflection of microwave beam) and the center of the rotating band and a starting position of .25 inches between the nose and the start of the barrel, the position of the rotating band when stopped is then 3.69 inches from the barrel face. The microwave pulses show the projectile to be stopped for approximately 4 milliseconds (2 cm on the trace) and then the projectile accelerates rapidly with the rise in chamber pressure. The rapid acceleration is seen more clearly in Figure 1.b., where an expanded time scale is shown.

The most important of the three interior ballistics segments, as far as sustained high torque seen by the rotating band is concerned, is the restart to muzzle exit portion. Fortunately, the time scale, when expanded (Figure 1.b.), has excellent resolution of the traces and can be reduced to the graph of Figure 3. Corresponding chamber pressure for each time is also obtained. A smooth curve is fit through the raw velocity data points and the equation of this curve generated. This equation can be differentiated to yield projectile acceleration down the tube for this segment.

The second segment (between stop and restart) has a relatively constant pressure and no projectile movement. Pressure, velocity,

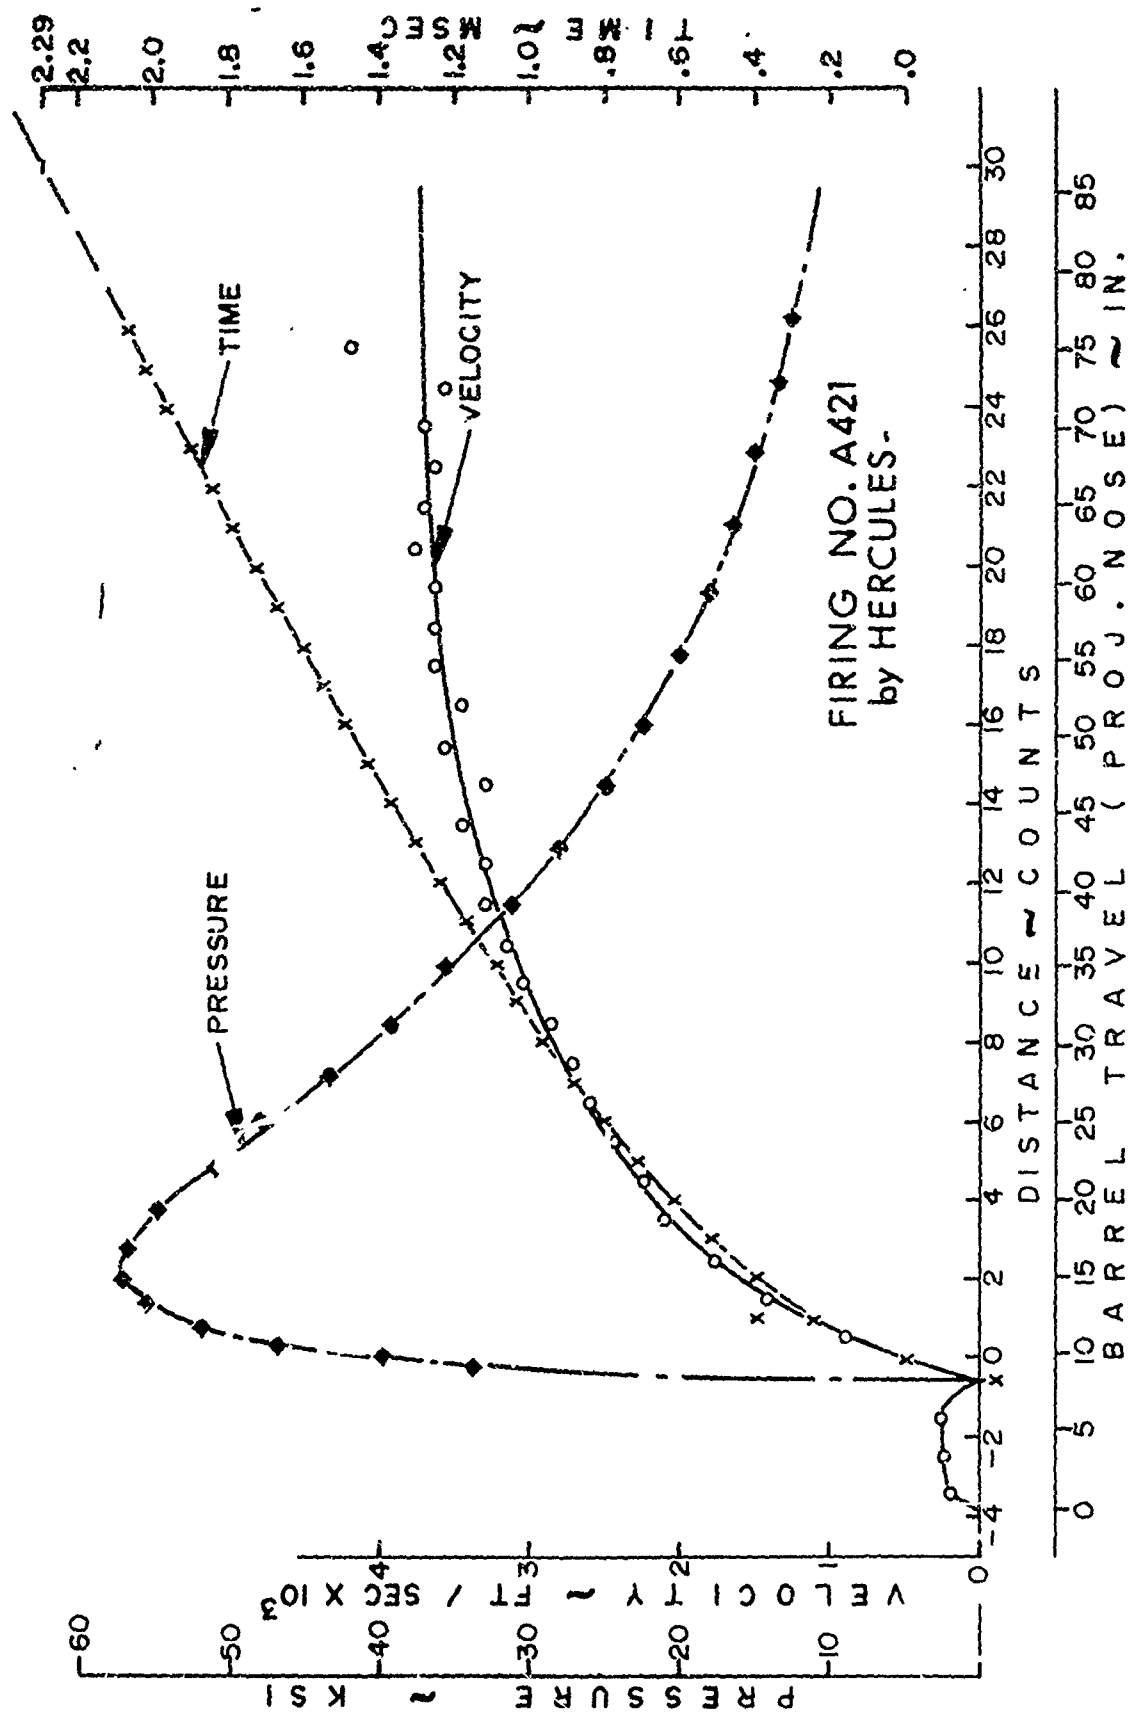

FIGURE 3. VELOCITY, PRESSURE AND TIME VS BARREL POSITION, AMCAWS 30 FIRING NO. A421

position, acceleration and time data points are easily generated for this segment.

The first segment (primer strike to stop) is the hardest to resolve to the point where ballistic data points can be obtained that have a high degree of confidence. The overall picture (Figure 1.a.) gives the time of occurrence and indicates some approximate values of position and time. The values obtained from the trace and other work done with booster performance enables "data" to be manufactured which should reasonably duplicate the performance of the round in the first segment. This data does not have as high a degree of confidence as the third segment data because of the poorer resolution, but torques are only seen in this segment for an extremely short time and projectile velocity is low, so possible inaccuracies in this segment of the data are not too important to the conclusions of this report.

Data representing the second segment was used as input for data generating program (Appendix B, AMCAWS 30mm Interior Ballistics). The program chiefly uses equations generated for position, velocity, and chamber pressure as functions of time for segments one and three and uses these equations to calculate the IB parameters for these segments. The program then links the data of the three ballistic segments and punches a complete data deck. This deck represents the nominal interior ballistics of the AMCAWS 30mm round, from primer strike to muzzle exit. The interior ballistics of the round are illustrated in

Figures 4 and 5. One result of obtaining acceleration by differentiating the smoothed velocity data can be seen by observing the slight discrepancy between the chamber pressure shape and the shape of the curve for acceleration. This problem is caused by an inability to more accurately resolve the original interferometer trace. The acceleration curve should be very close to the 'correct' curve and it is not felt that the results of the computer program are in any way unduly compromised.

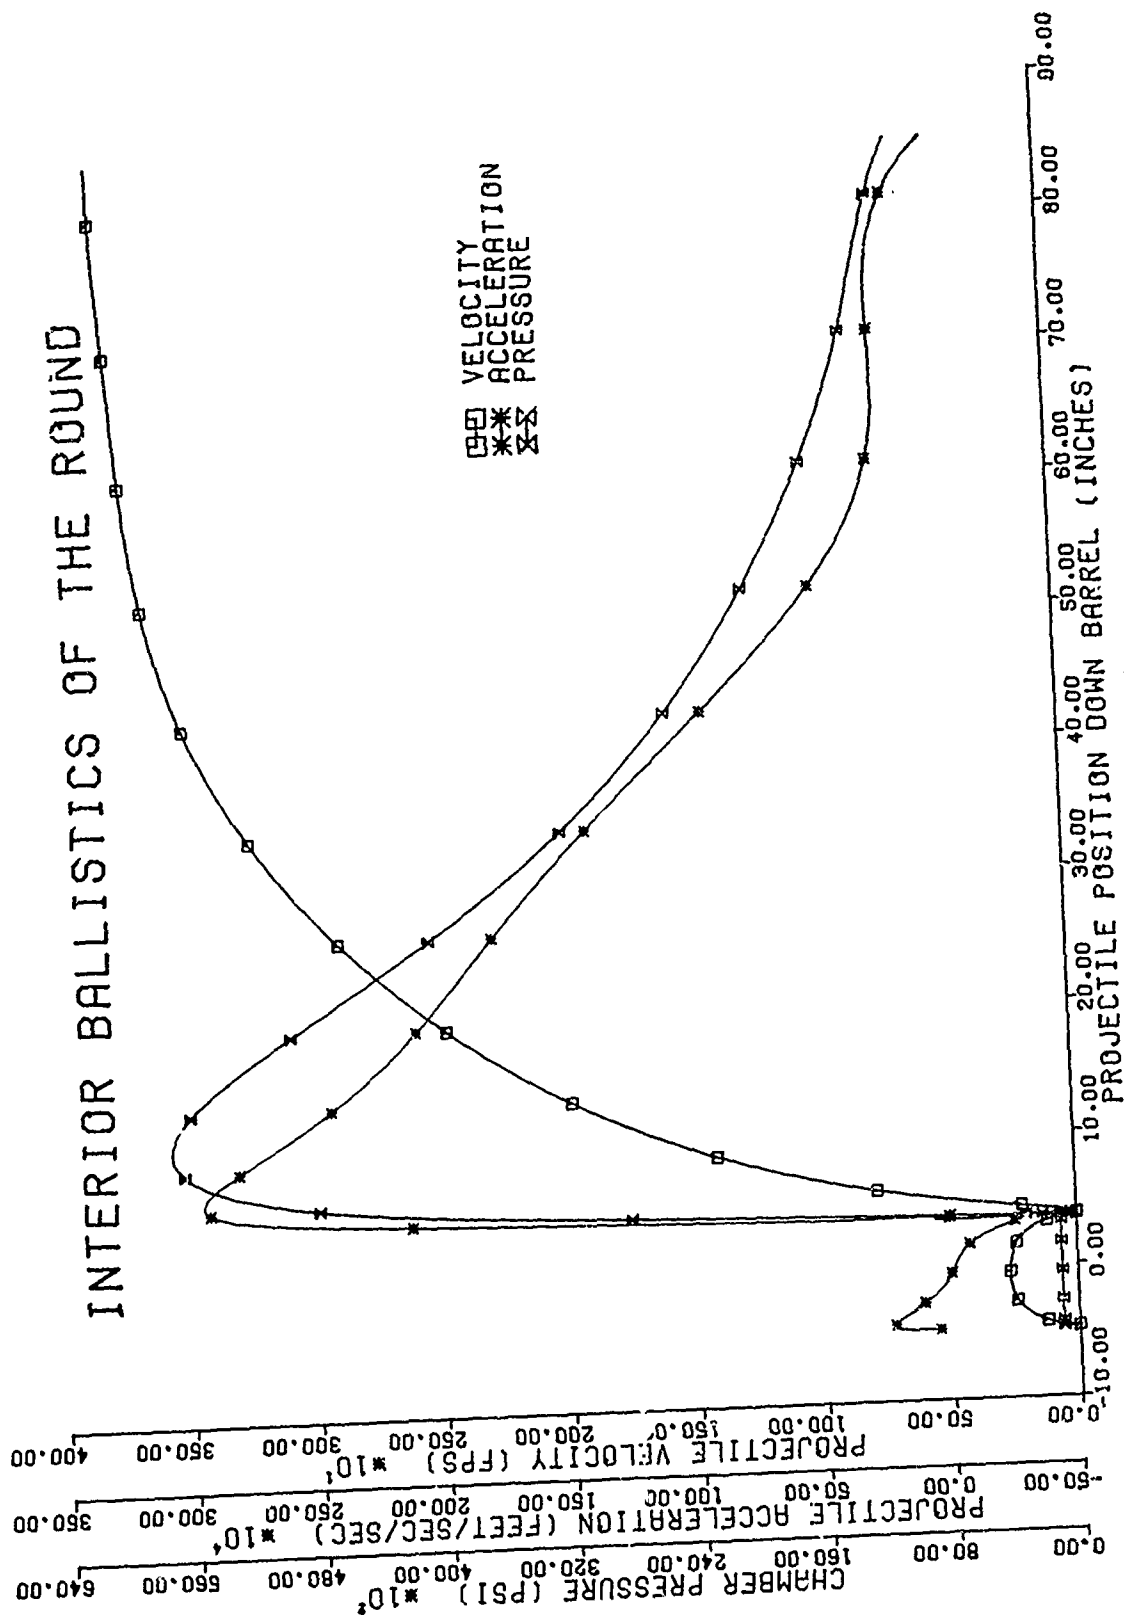

FIGURE 4

INTERIOR BALLISTICS OF THE ROUND

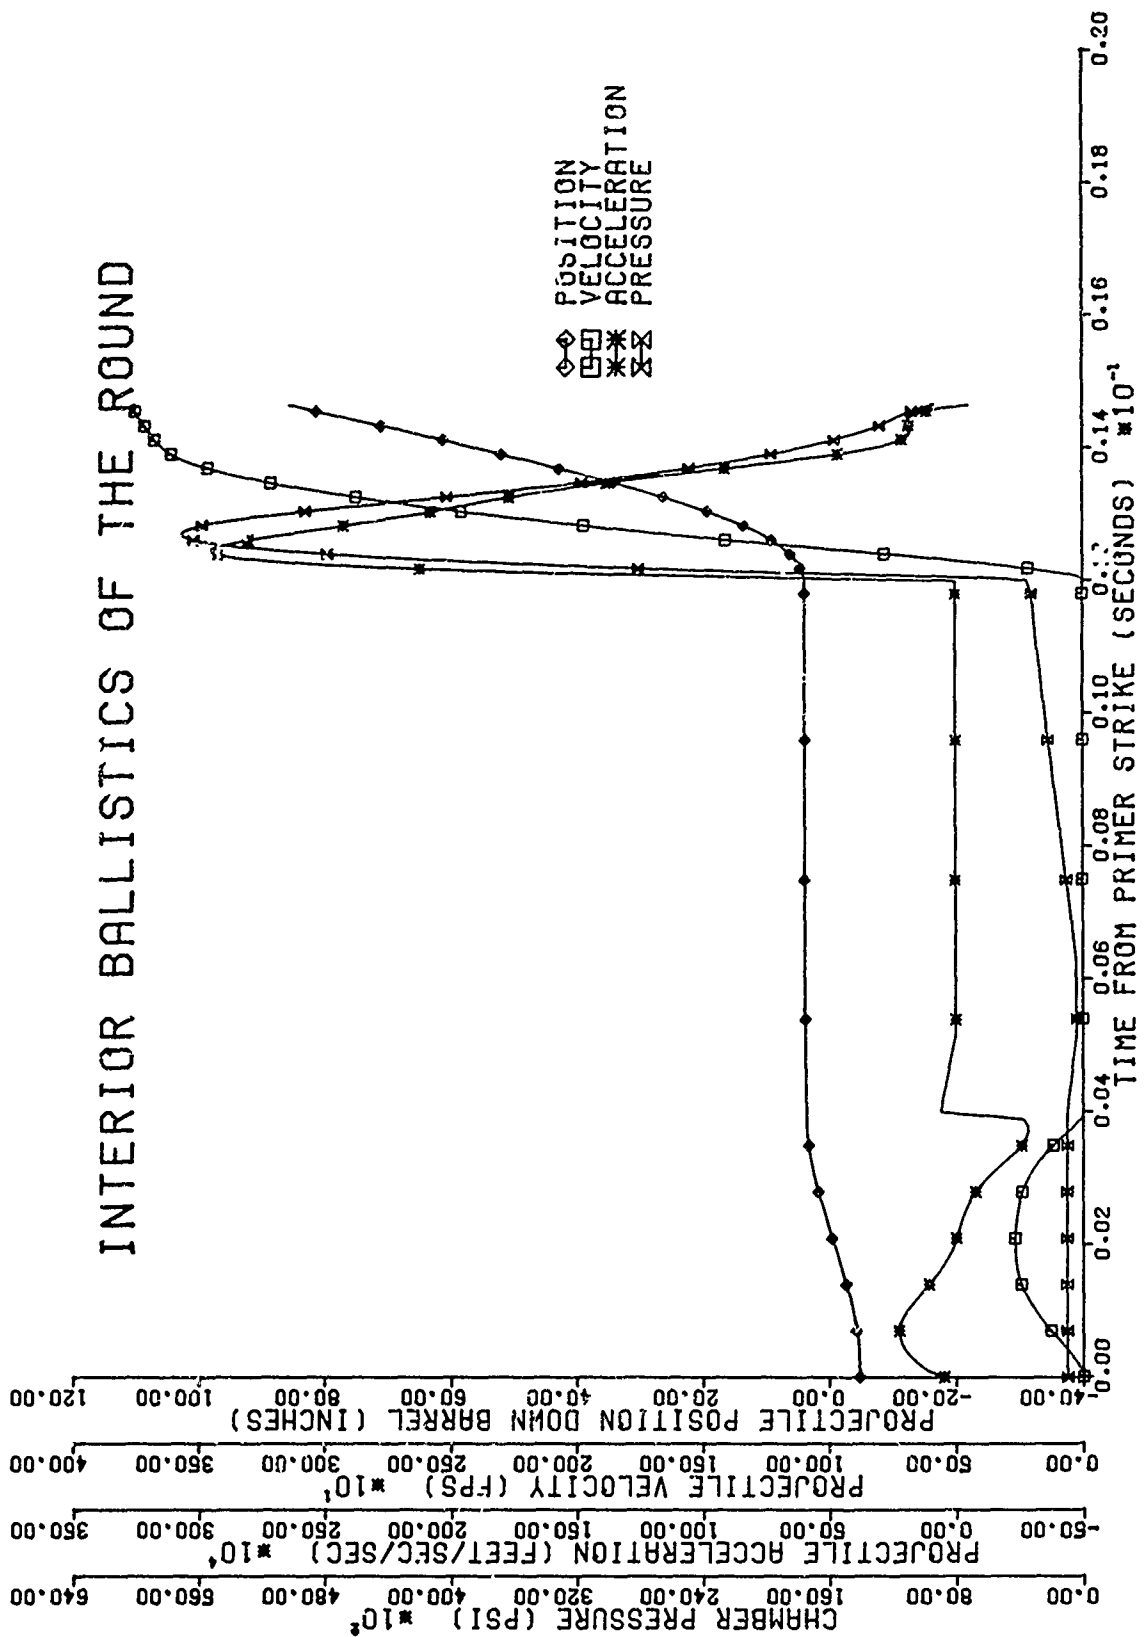

FIGURE 5

DEVELOPMENT OF TORQUE AND STRESS EQUATIONS

Figure 6 shows a rifling curve in the gun tube. Y is the arc length subtended by θ , R is the nominal 30MM radius (.59175 inches) and X is the distance down the bore the rotating band has traveled. Assuming no shear in the rotating band, the rotation of the projectile after traveling X inches is θ .

Torque and stress relationships will be obtained using the equation,

$$\text{Torque} = I_{\text{polar}} \times \frac{d^2 \theta}{dt^2}$$

therefore $\frac{d^2 \theta}{dt^2}$ is a quantity of much interest. From Figure 6,

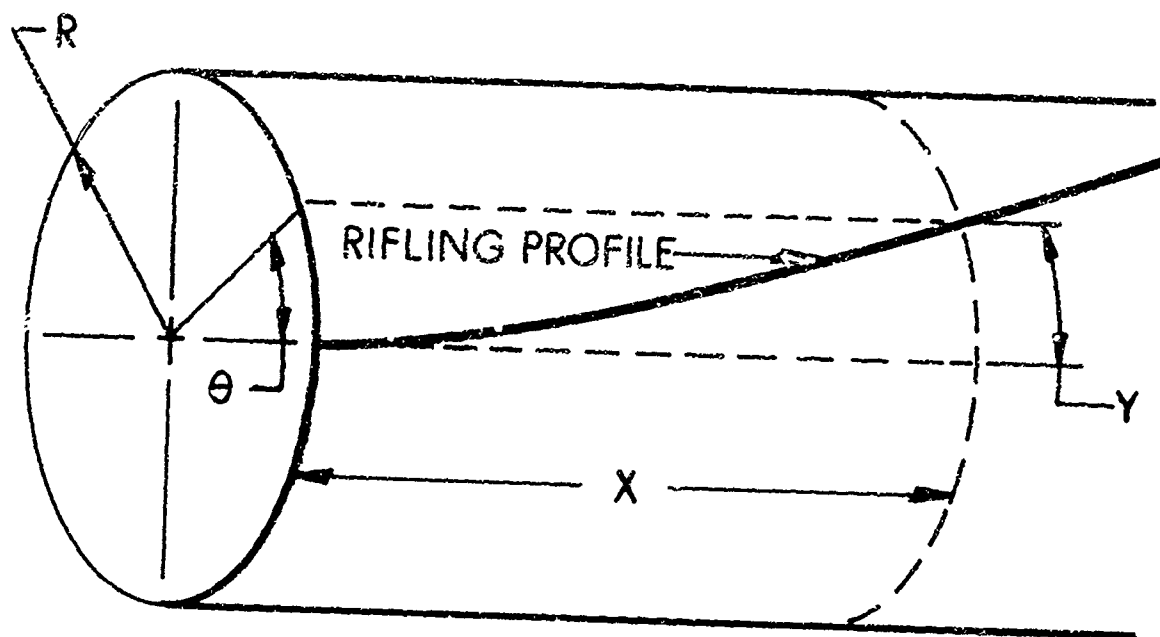

$$R\theta = Y$$

$$\frac{d(R\theta)}{dt} = R \frac{d\theta}{dt} = \frac{dy}{dt} = \frac{dy}{dx} \times \frac{dx}{dt}$$

but,

$$\frac{dx}{dt} = \text{velocity of projectile down the tube, thus}$$

$$\frac{d\theta}{dt} = \frac{1}{R} \left[\frac{dy}{dx} (\text{velocity}) \right]. \text{ Differentiating again}$$

R - NOMINAL 30MM RADIUS
X - DISPLACEMENT
 θ - ANGLE OF ROTATION
Y - ARC LENGTH SUBTENDED BY θ

RIFLING CURVE LAYOUT

FIGURE 6

$$\begin{aligned} \frac{d}{dt} \left[R \frac{d\theta}{dt} \right] &= \frac{d}{dt} \left[\frac{dy}{dx} \frac{dx}{dt} \right] = \left[\frac{dy}{dx} \frac{d^2x}{dt^2} + \frac{dx}{dt} \frac{d^2y}{dx^2} \frac{dx}{dt} \right] \\ &= \left[\frac{dy}{dx} \frac{d^2x}{dt^2} + \frac{dx}{dt}^2 \frac{d^2y}{dx^2} \right] \end{aligned}$$

However,

$\frac{d^2x}{dt^2}$ = acceleration of projectile down tube, thus

$$\frac{d^2\theta}{dt^2} = \frac{1}{R} \left[\frac{dy}{dx} (\text{acceleration}) + \frac{d^2y}{dx^2} (\text{velocity})^2 \right]$$

Summarizing,

$$\theta = \frac{1}{R} \left[\gamma \right]$$

$$\dot{\theta} = \frac{1}{R} \left[\frac{dy}{dx} \text{ velocity} \right]$$

$$\ddot{\theta} = \frac{1}{R} \left[\frac{dy}{dx} \text{ acceleration} + \frac{d^2y}{dx^2} (\text{velocity})^2 \right]$$

Values for velocity and acceleration (as discussed in the INTERIOR BALLISTICS portion of this report) are available to the BARREL/TORQUE COMPARISONS program so that with the proper equation of the rifling for the barrel under consideration $\ddot{\theta}$ can be determined for any position or time.

Given the values for $\ddot{\theta}$, the other calculations are quite straightforward. Torque is obtained from the relationship

$$T = I_{\text{polar}} \ddot{\theta}$$

Torque, however, can be considered to be the result of a distributed force acting at the rotating band (nominal radius to rotating band is .59175 inches). The total force acting to create the torque is then

$$\Sigma F = T/R.$$

The area upon which this total force acts is, of course, the bearing faces of the engraved rotating band (Figure 7). The bearing stress is then

$$S_{\text{bearing}} = \Sigma F / \Sigma (\text{bearing face area}).$$

Likewise, the shearing stress on the band is then

$$S_{\text{shear}} = \Sigma F / \Sigma (\text{shearing face area}).$$

The sketch of Figure 7.a. shows the dimensions of a rotating band that was fired through a RIA barrel. The nominal groove depth of the RIA barrel is .019 inches so the summation of bearing face areas is .137 square inches. The Hercules barrel has a groove depth of .025 inches so its total bearing face area is .180 square inches. The total shear for the recovered projectile is .677 square inches.

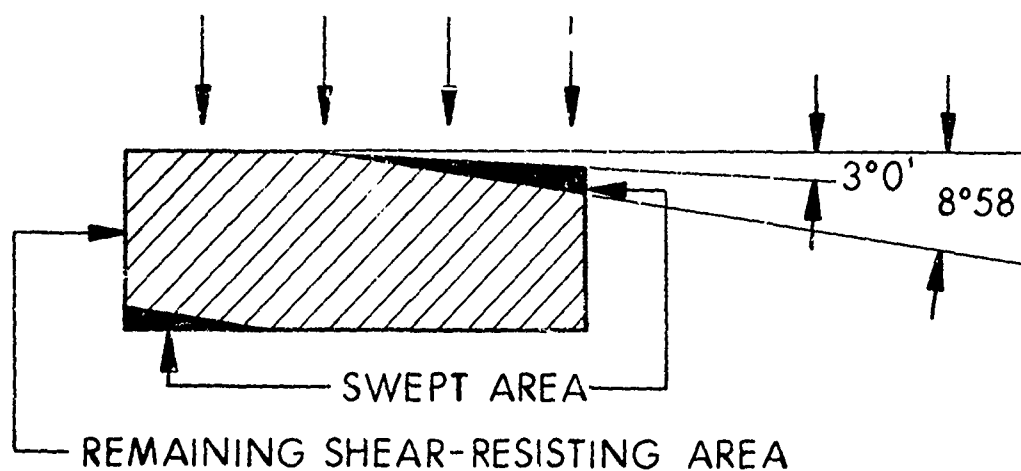

FIGURE 7-B

OBSERVATIONS

There are any number of ways to interpret the numbers generated by the Barrel/Torque Comparisons computer program. There is also a high probability that any arbitrary interpretation and the corresponding conclusions as to predicting the success of the rotating band and barrel twist combination will be incorrect. The most important aspect that must be considered when evaluating the program results and making useful conclusions is the actual mechanism of rotating band failure that may occur.

Factors which may affect the ultimate success of a rotating band probably include a combination of factors such as (1) peak torques, (2) time duration of high torques, (3) driving edge pressure, (4) area remaining that resists shear, (5) band properties, (6) band melting, (7) barrel wear, and probably several other considerations.

The way in which these named and unnamed factors interact in the AMCAWS 30mm system to determine the final condition of the rotating band is, of course, the mechanism of rotating band failure. Determining the actual mechanisms of failure for the rotating bands of high performance ammunition is certainly a large scale test and research program that is far beyond the scope of this report. A literature search (unclassified) has been relatively unsuccessful in uncovering work that specifically deals with copper rotating band failure in small to medium

calibers. What is primarily the scope of this report is to provide a basis for selecting a replacement for the RIA twist barrels. Hopefully, with the fabrication and availability of RIA, $N = 1.6$, constant twist, and Hercules barrels, some correlation between the program results and actual firing test results can be developed. Developing such a correlation is a secondary portion of the scope of this report. If a correlation between actual results and some combination of numbers generated by the program can be found, it might be able to act as a quick and coarse means of evaluating barrel twist suitability for future or proposed high performance medium caliber weapon systems. The remainder of this report is written with that in mind. Some general discussion of barrel twists is then pertinent.

Any gain twist barrel is sensitive to the interior ballistics of the round. A round with slightly delayed peak pressure and thus delayed peak acceleration will be in a steeper portion of the gain twist curve and therefore higher than optimum torques develop. The present RIA barrel configuration has good torque characteristics for certain ballistic performance, unfortunately they are not similar to the performance of the current AMCAWS 30mm round.

Another problem common to gain twist barrels is the rifling angle sweeping action that reduces the shear area of the rotating band and continually puts high bearing loads on the forward portion of the band. This sweep is due to the constantly increasing rifling angle

in the gain portion of the barrel and as illustrated in sketch of Figure 7.b. The 3° initial twist for the $N = \underline{\quad}$ barrels was chosen because it was felt the almost 9° sweep on the RIA barrel was one of the major contributing factors to the failure of that barrel-rotating band combination. The fact that there is evidence of band stripping on the RIA barrel but no in-flight instability of the round tends to indicate the bands finally do strip after the round has attained sufficient spin to be stable. The higher spin rates necessary to stabilize the round can only be imparted to the round in the muzzle portion of the gun tube where the rifling angles are high. Thus, it appears the bands do strip in the muzzle region of the RIA barrel, after experiencing most of the $8^\circ 58'$ sweep.

The behavior of gain twist barrels, especially with regard to increasing exponents, can be seen in Figures 8 and 9. The peak torque values occur later with increasing exponents. The peak values are less with increasing exponents but the curve itself is much flatter. These effects are particularly noticeable in the torque vs. displacement curve, Figure 8.

The barrel that appears most attractive, of the gain twist barrels considered, is the $N = 1.6$ barrel. A constant twist exit portion is desired so that the torque is low at projectile exit. Four to five calibers of constant twist should be long enough to minimize any perturbations that might be caused by a high torque at exit. The

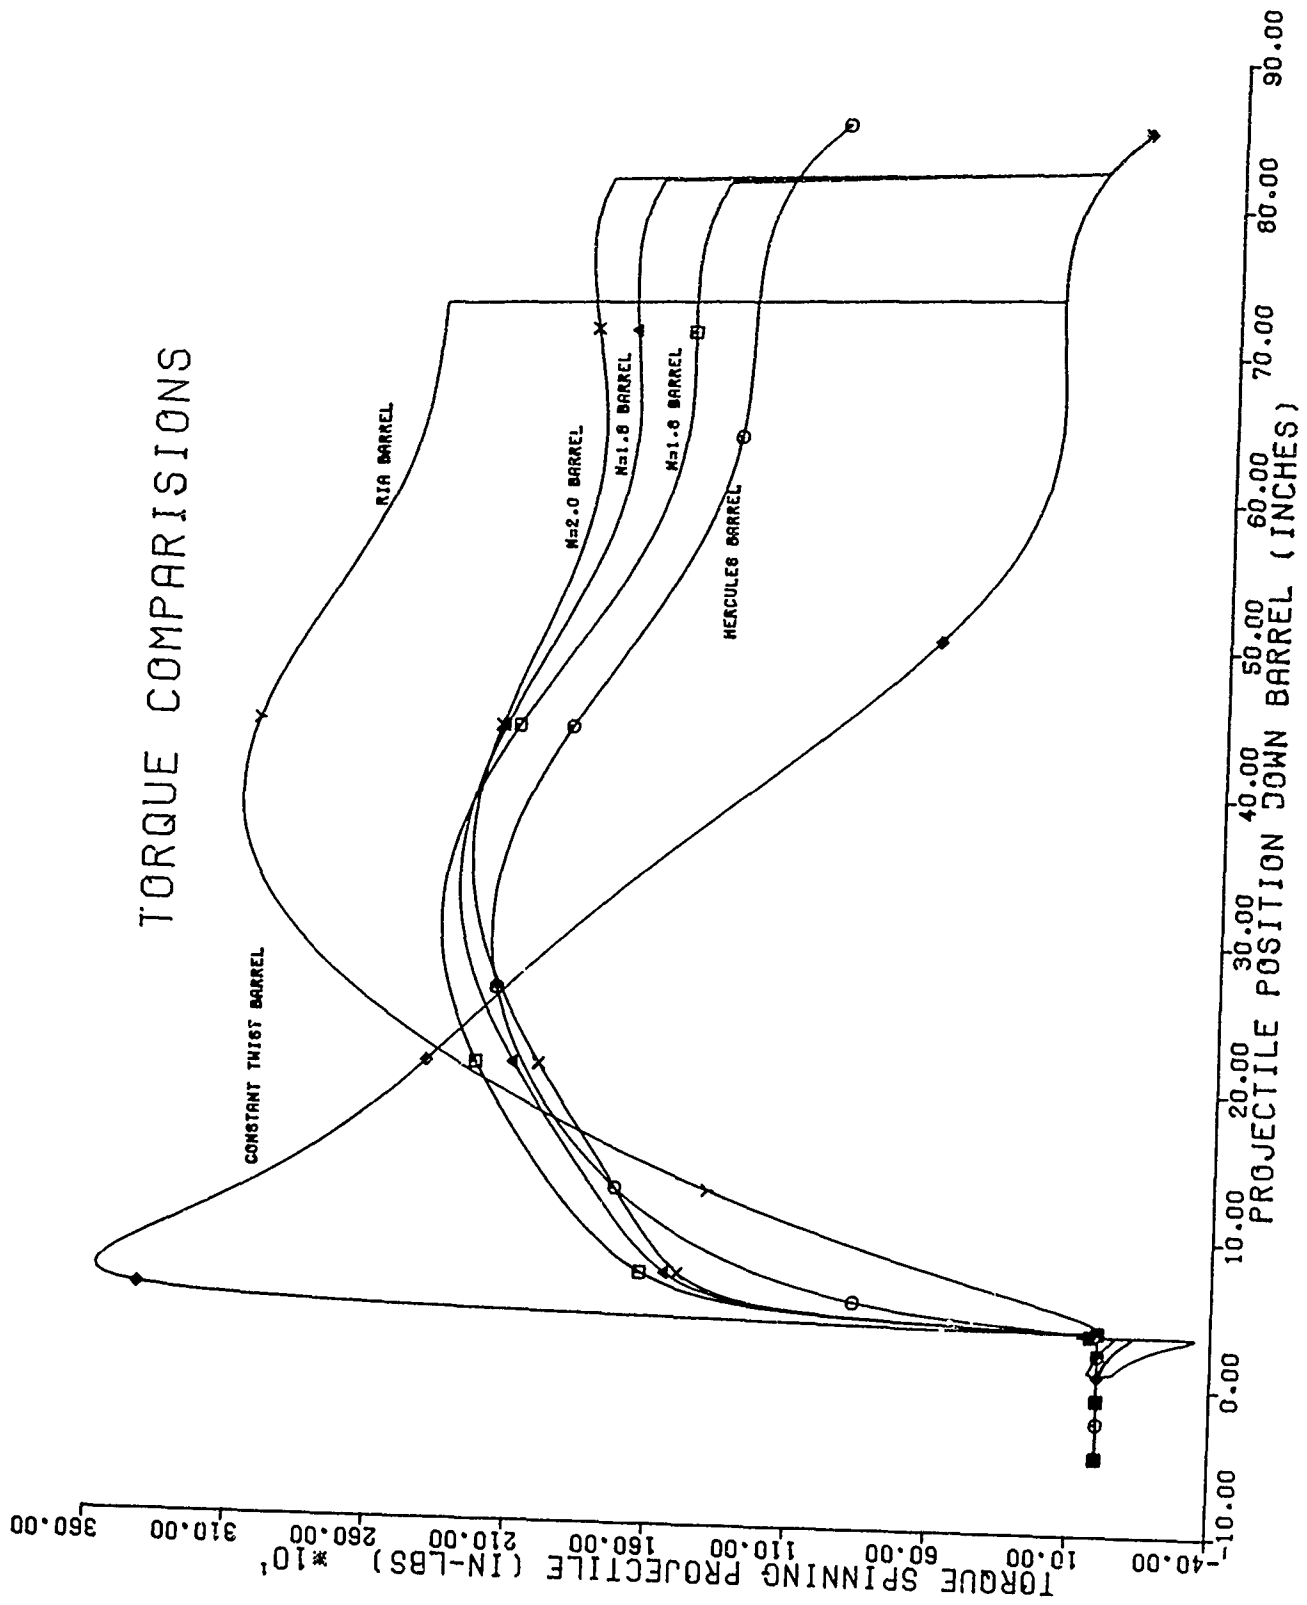

FIGURE 8

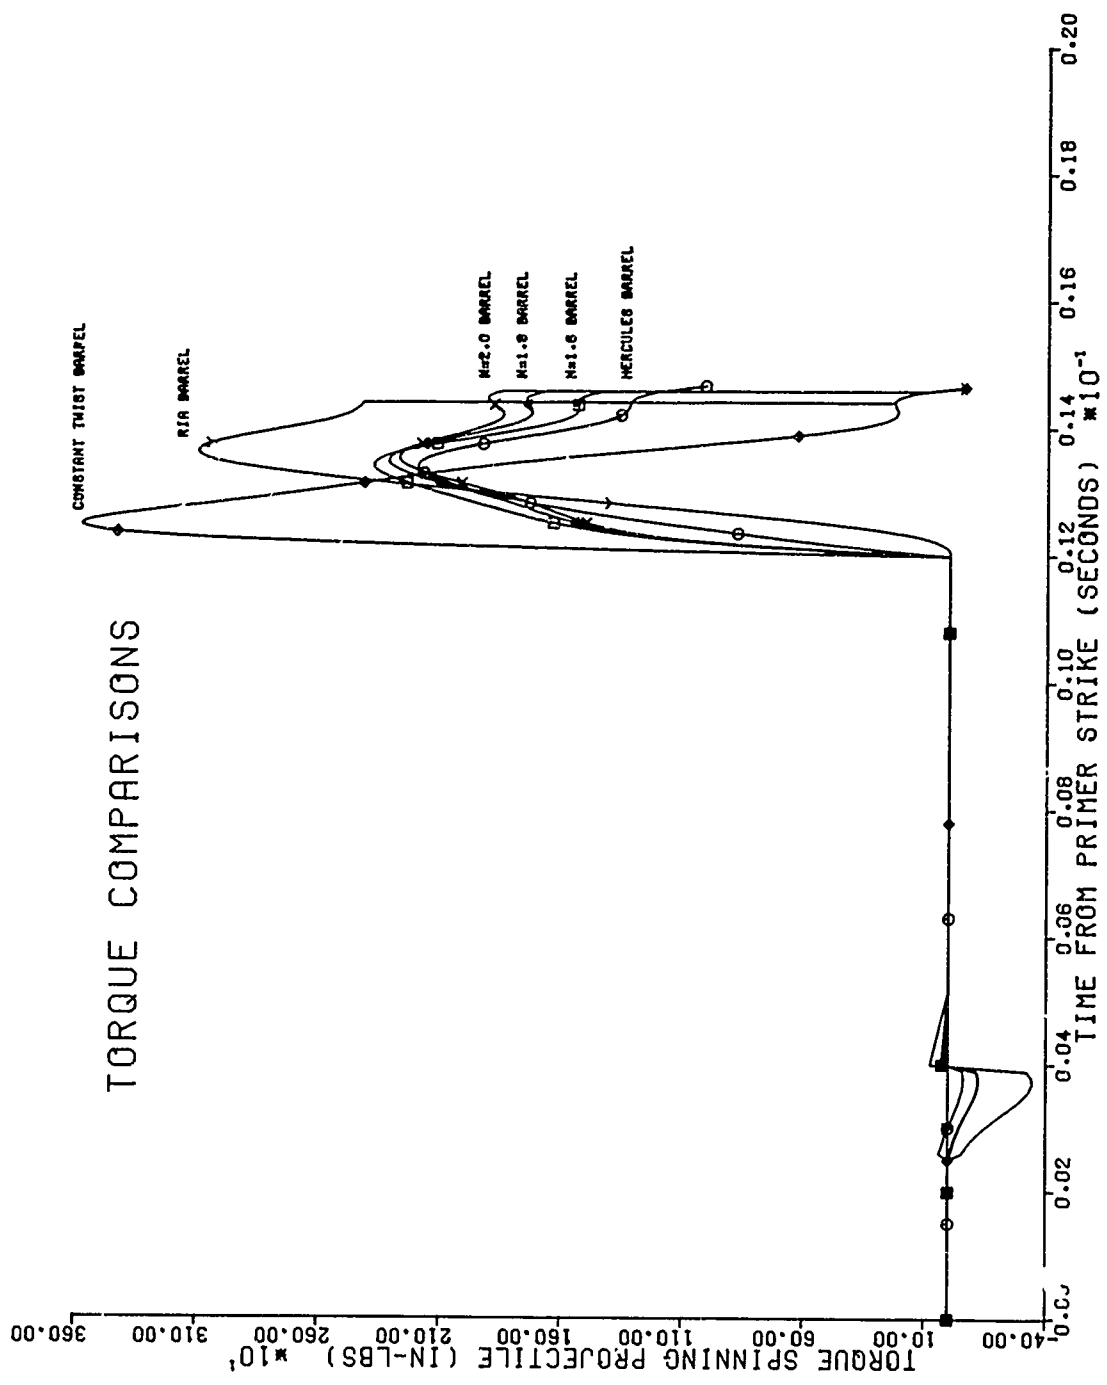

FIGURE 9

N = 1.6 barrel has a slightly higher peak torque than the N = 1.8 or the N = 2.0 barrels, but it should handle slight round-to-round ballistic changes better.

Constant twist barrels are, compared to gain twist, relatively insensitive to interior ballistic changes. Constant twist causes none of the sweeping action found in gain twist barrels, so the shear area is always at a maximum for any given exit angle. Unfortunately, constant twist barrels exhibit higher torques than their gain twist counterparts. The time duration for the peak torque region is correspondingly less. This is shown by the sharper peak on the torque vs. displacement curve (Figure 8).

Constant twist barrels can also be fabricated with more manufacturing techniques than can gain twist barrels. Broaching, swaging, or hammer forging (which are possible only with constant twist) are generally cheaper than hook tooling or the more exotic ECM techniques, especially in a quantity production environment. The barrels used to date in the AMCAWS 30 program have all been hook tooled.

FIRING TEST

Completion of the fabrication of an $N = 1.6$ and a constant twist barrel, combined with the availability of an RIA twist barrel, allowed a firing test to be conducted that was designed to evaluate the three band/barrel combinations. A series of 28 shots with basic Mann barrel instrumentation (chamber pressure, round action time, velocity) was fired with down-range photographic equipment set up (Figure 10) so that in-flight pictures of the fired AMCAWS 30 rounds could be obtained. The firing data for these rounds is listed in Table 1. The ammunition used is Lot X05. All three barrels had less than 20 rounds each fired through them when the test began.

The pictures obtained were of excellent clarity. The three pictures chosen for each barrel for inclusion in this report are very representative of all the pictures taken.

Rounds 63, 68, and 72 are rounds fired through the RIA twist barrel. These pictures show the bands completely stripped. The rounds are stable as shown in the pictures. Rounds fired through RIA twist barrels have always targeted well. This reaffirms the belief that these bands stripped only after a large enough spin rate was obtained for the round to be stable.

Rounds 74, 75, and 80 are rounds fired through the constant twist barrel. The bands on these projectiles are in excellent condition.

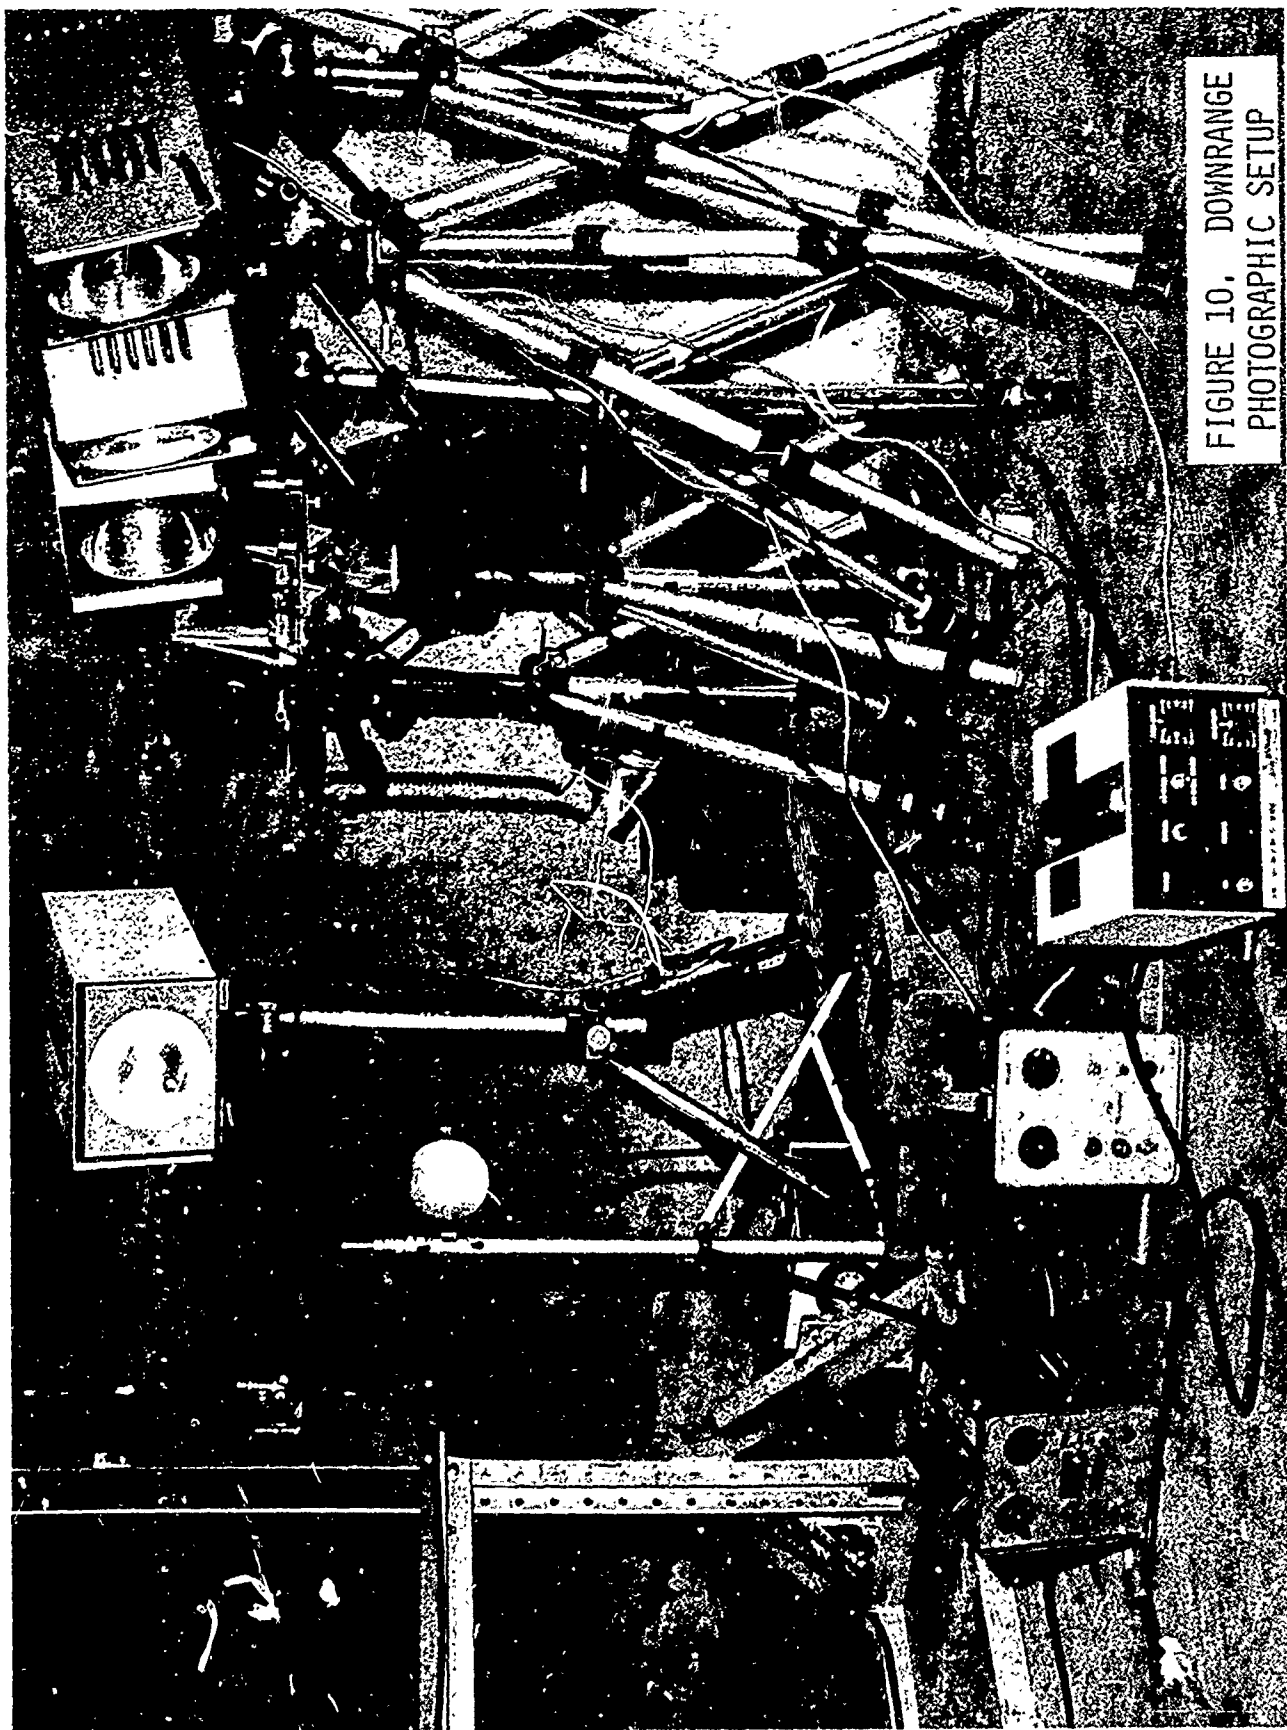

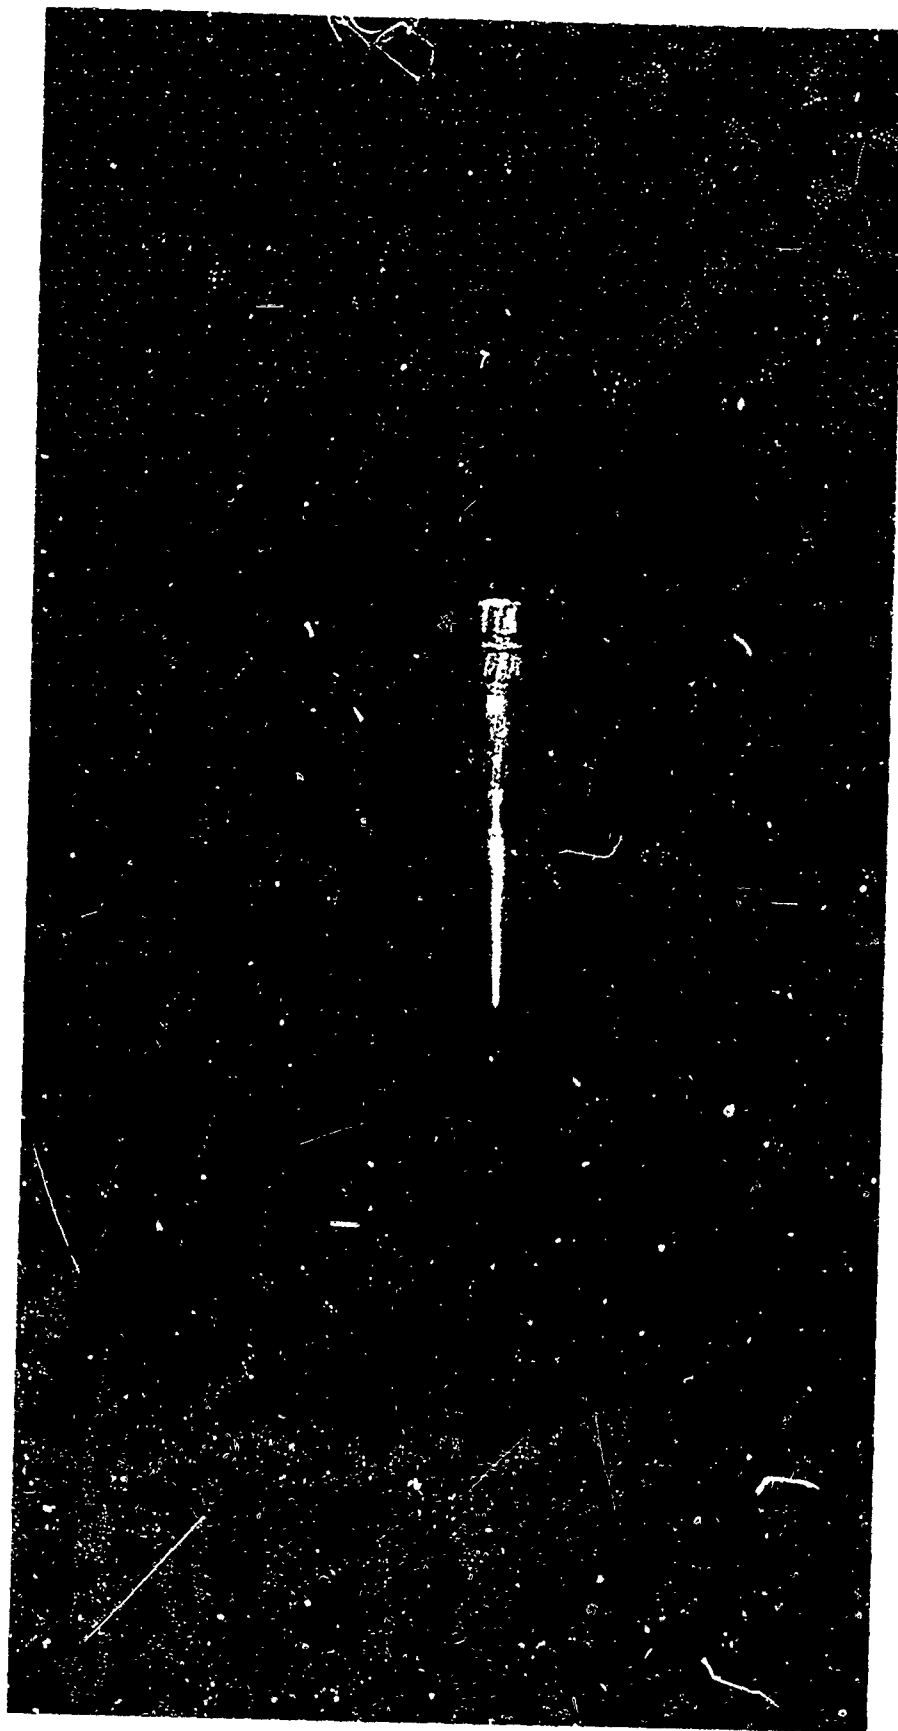

FIGURE 10, DOWNRANGE
PHOTOGRAPHIC SETUP

Rounds 86, 87, and 88 are rounds fired through the $N = 1.6$ twist barrel. These bands are also in good condition. The gain twist sweep mentioned earlier is easily seen. The driving edge face is in very good condition for the entire width of the band.

Table I. In-Flight Pictures for Rounds Fired Through RIA, Constant, N = 1.6 Barrels

EVALUATION OF RESULTS AND PREDICTIVE MODEL

The initial decision to fabricate the $N = 1.6$ barrel was made after the results of an early version of the Barrel/Torque Comparisons program were evaluated and the $N = 1.6$ barrel appeared to offer a significant reduction in peak torque and it was noted the torque curve approached the curve for the Hercules barrel (which was known not to strip bands).

The decision to fabricate a constant twist barrel was made because it was felt that so basic a barrel type should be evaluated with actual firings. Historical inertia and the high peak torque values led most everyone involved in this decision to feel this barrel would most certainly fail the band.

The firing tests and in-flight pictures indicate that future barrels fabricated for the AMCAWS 30 program, using current interior ballistics and copper rotating bands, should have constant twist or the $N = 1.6$ twist. The primary objective of this effort, choosing a replacement for the RIA twist barrel, has been met with that recommendation.

The secondary objective of this report, providing some coarse predictive model for evaluating the suitability of different band, interior ballistic, and twist combinations, is not as directly met. A model such as that will necessarily be simplistic since, as stated,

the "precise" mechanism of rotating band failure for this type of high performance ammunition has not been explicitly determined.

The model must also be simplistic because it is trying to generalize from a small amount of data and a limited firing test. The approach that will hopefully result in constructing the predictive model is one of essentially working from both ends to the middle (Figure 20). One end is the computer program that assumes no band failure and calculates the values listed in the data matrix. The other end is the result of the firing test. The middle is the model that will evaluate the computer program output and predict the same results as occurred in the firing test.

The model presented here suggests that two things should be considered; (1) the peak stress values must be able to be sustained by the rotating band, and (2) the time over which the high values act is very important.

The first consideration seems somewhat obvious. The band properties must be able to resist the peak shear and bearing loads. Shear stresses for the barrels considered do not exceed 10,000 PSI so failure in shear does not appear to be a problem. The bearing stresses are much higher, approaching 40,000 PSI.

The difficulty in determining if the peak bearing stress values exceed the band properties is finding data on band properties. Pub-

PREDICTIVE MODEL APPROACH

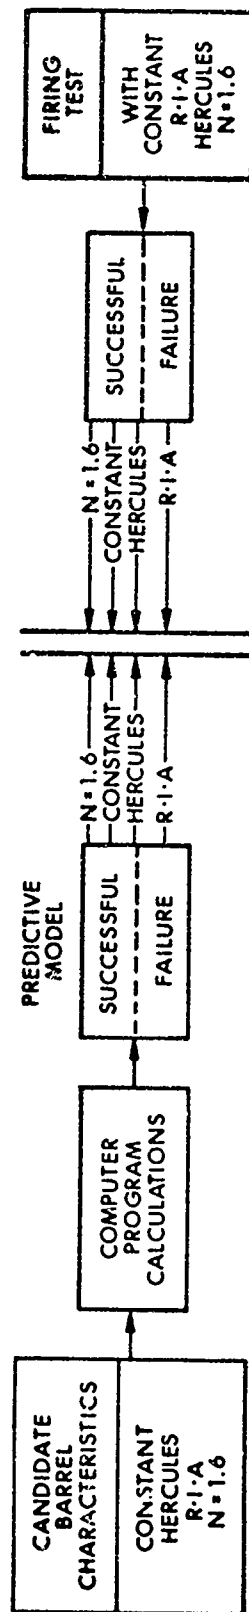

FIGURE 20

lished data from materials testing usually indicates that all rotating bands for high performance ammunition should fail. Most materials testing is done at a rate that does not begin to approach the rate of application of stresses in a gun. High strain rate tests do not usually result in data with easily comparable units, such as PSI. Rate of application certainly affects the ultimate limits of bearing strength and shear strength for the band material. One published value¹ suggests 20,000 PSI as an allowable copper rotating band bearing stress, but the three successful barrels exceed that value by 11% to 65%. None of the barrels considered are less than 20,000 PSI in bearing. The constant twist barrel has a peak bearing stress of 33,200 PSI, so that might be considered a minimum for a range of values that describe the ultimate limit for rotating band bearing stress. The indications that the band are stripped well down the RIA barrel tend to suggest that the band withstands even the 38,000 PSI peak bearing stress of the RIA twist barrel successfully.

The peak torque, bearing stress, and shear stress values are listed in Table 2. These are the peak values computed in the program. Actually, however, the peak values for the constant or the $N = ___$ barrels are not listed. The nonspinning rotating band moving at about 200-250 fps engraving onto the 9° or 3° twist theoretically (since a no shear condition is assumed) produces infinite peaks. These peaks

PEAK TORQUE AND STRESS VALUES

TABLE 2.

last for such a small time period that they can be neglected. The print-out shows torque for the constant twist barrel is 0.0 in-lbs when the band is .816 inches into the barrel and 57.1 in-lbs at a band position of 1.124 inches. The time increment is .1 milliseconds. These values infer the time duration for the very high torque values are probably on the order of microseconds. The Gun Tube Handbook² refers to a five microsecond duration for the decay of infinite torque to "acceptable" values for a 37mm gun with 1.0 inch free run and a $y = px^{1.625}$ rifling profile. This background is presented in an effort to demonstrate that the time duration of peak values is important (again, there is also a rate of application relationship).

Bearing stresses for the six barrels compared appear to be the most critical values coming out of the program. The range of these values is very high relative to all published data (directly comparable or not) for properties of this class of copper. Bearing stress also relates to the amount of displacement the driving edge experiences, which could significantly change the remaining shear area. This might possibly reduce it to a critical region. Band melting might be accelerated by higher bearing stresses and the higher frictional forces. These parameters, which can be associated with bearing stress, are also felt to be rate dependent.

²AMCPM 700-252, Engineering Design Handbook, Gun Series, Gun Tubes, February 1964.

The idea of time duration and rate dependence is the reason a comparison of the integral of bearing stresses with respect to time is offered as the second test in this two-step model. The program uses a trapazoid summation to integrate torque, bearing stresses, and shear stresses with respect to time and position. The values are listed in Table 3.

Once again, a number which represents the dividing line between success and failure, for the integral test, is not readily available. The dividing line value appears to be between 48 PSI-sec and 55 PSI-sec, assuming the RIA barrel does not cause band failure due to the first test.

The proposed predictive model utilizes: (1) a computer program to calculate stress values caused by proposed interior ballistic performance acting on the candidate rifling profiles, (2) rotating band materials properties that can be meaningfully compared to the calculated stress values, and (3) a comparison of the integrals of the bearing stress versus time curves for the candidate barrels. This predictive model, based on very limited data and without precise knowledge of the mechanism of band failure that actually occurs, is somewhat incomplete. The model will provide a basis for evaluating any significantly different interior ballistic performance, such as when AMCAWS 30 goes to a non-stop mode. While the model will be refined and corrected with more firings and additional research, it now provides a better basis for selecting a barrel twist than was available previously.

TABLE 3

CONCLUSIONS AND RECOMMENDATIONS

The Barrel/Torque Comparisons computer program can easily be changed to provide comparisons of many possible barrels with a set of nominal ballistics data or comparisons of one barrel with a range of ballistic performance. This is a useful design tool so that someone charged with releasing a barrel drawing can do so with some assurance that the twist profile appears compatible with the interior ballistics of the round. An advanced gun and ammunition development program, such as AMCAWS 30, should check barrels about to be released against current interior ballistic performance.

The predictive model is admittedly simplistic, based, as it is, on limited data, limited experience, and limited intuition. The model is not, hopefully, one of the arbitrary interpretations discussed under Observations. Work, to whatever degree possible, should continue on refining such a predictive model as it will fill a very real need in designing one aspect of the gun-ammunition interface.

The success of the $N = 1.6$ barrel as indicated by the values coming out of the computer program and the firing tests, is due to its hybrid design. The initial rifling angle of 3° is a very important design element to reduce the total sweep experienced by the rotating band while the 1.6 exponential gain allows low band stresses throughout the barrel. The $N = 1.6$ barrel essentially takes the zero band sweep

aspect of a constant twist barrel and combines it reasonably successfully with the low peak values associated with gain twist barrels.

The goal of the initial effort of this work was to provide a replacement for the unsuccessful RIA twist barrel. The recommendation of the constant or the $N = 1.6$ twist barrels with the current AMCAWS 30 interior ballistic performance meets that goal. There is a very high degree of confidence in those recommendations since they were actually fired. Looking ahead in the AMCAWS 30 program to non-stop ballistics and plastic rotating bands, a secondary goal of evaluating barrel/band combinations without fabrication and firing developed. The predictive model presented is a first step in meeting that goal.

Specific conclusions and recommendations follow:

CONCLUSIONS:

1. Evaluate barrels about to be fabricated with current interior ballistics performance.
2. Current (May 1975) ballistic performance indicates $N=1.6$ or constant twist barrels should be used.
3. Rotating band sweep on gain twist barrels is a critical parameter that must be considered when suggesting a new gain twist function.
4. Rotating band sweep due to gain twist limits the rotating band width (width in the axial direction) that can be effectively used. Wider bands with gain twist barrels do not always have better survivability.

RECOMMENDATIONS:

1. Obtain better and more useable data on high rate properties of rotating band materials.
2. Refine the rotating band predictive model.
